Falls prevention in older adults
Assessment and management

Background
Falls increase with age, with substantial patient harm resulting in high healthcare utilisation. High level evidence exists for a range of effective falls prevention strategies.

Objective
To provide an evidence based update of falls prevention recommendations, applicable to the primary care setting.

Discussion
For older adults in the community, exercise programs and vitamin D supplementation in those with deficiency are highly effective in preventing falls. Psychoactive drug withdrawal, home visits, vision optimisation and a multifactorial approach are also effective. In residential aged care, routine vitamin D supplementation is highly effective in preventing falls and fractures. General practitioners are well placed to identify those at risk of falls and implement prevention strategies utilising other healthcare professionals as required. The general practitioner’s role in educating and supporting patient behaviour change is critical to the uptake of falls prevention recommendations.

Keywords
elderly; accidental falls; prevention; exercise, vitamin D

Falls in older people are a major concern in terms of disability, institutionalisation, mortality and socioeconomic burden. An Australian study found 8% of women aged in their 40s, 14% in their 50s, 25% in their 60s and 40% in their 70s had experienced a fall in the previous 12 months. In older adults, up to 30% of falls can result in moderate to severe injuries, such as lacerations, hip fractures and head trauma, resulting in an increased risk of early death. A fall may lead to a fear of falling, avoidance of daily activities, social isolation, lowered quality of life and can precipitate a move to residential aged care.

In the past decade, the falls prevention evidence has expanded and many guidelines now exist. Despite this, there remains a national trend of increasing fall related hospitalisations, which, if unchanged, will result in escalating healthcare costs. Improving outcomes requires addressing evidence practice gaps for individual patients in addition to a systemwide approach. General practitioners may identify patients who will benefit from fall prevention measures, develop and implement treatment plans with other health professionals and support patient uptake of recommendations. An Enhanced Primary Care plan may facilitate implementing falls prevention strategies.

Why older people fall
Many falls are multifactorial in nature and linked to both patient specific and environmental risk factors. Key intrinsic risk factors are age, sensory decline, reduced lower limb strength and comorbidity. Cognitive impairment, even subtle deficits, increases risk. A single identifiable major factor accounts for up to 20% of falls.

Assessment of falls and risk factors
The strongest predictors of risk are previous falls, with injurious falls and a walking or balance difficulty increasing risk even further. Screening balance tests can help identify those with deficits who will benefit from an exercise program (Table 1). High risk patients may require a more complex multifactorial assessment.

Key components of a multifactorial assessment include:
- a detailed falls history, medication review, risk factor assessment including osteoporosis, urinary incontinence and cardiovascular disease
- physical examination including gait and balance, neurological and cognitive function, lower limb strength, visual acuity, feet and footwear
Falls clinics apply this model and the evidence shows that it achieves a reduction in falls, and improved mobility, balance and confidence.  

**Single strategies**

**Exercise programs**

The link between exercise and decreased falls in older people living in the community is well-established. There is also good evidence that disability can be reduced by well-designed exercise in this population. There have been four systematic reviews and a number of more recent trials that have demonstrated that well-designed exercise can reduce falls in older people living in the community.  

Systematic reviews have also identified that tai chi can reduce falls by 37% and the New Zealand developed, Otago Exercise Programme, by 32%. The Otago Exercise Programme also significantly reduces the risk of death.  

**Characteristics of effective programs from the largest and most recent review are outlined in Table 4.**

Exercise uptake can be hampered by concerns about increased pain or lack of efficacy, however recommendation from the GP significantly increases uptake.

</tbody>
</table>

* Consider cardiologist referral if cardiogenic syncope is suspected

Falls clinics apply this model and the evidence shows that it achieves a reduction in falls, and improved mobility, balance and confidence.
**Vitamin D**

Vitamin D supplementation for older adults with deficiency is an effective and simple strategy for fall and fracture prevention, with fracture benefits persisting with increasing age. Vitamin D supplementation can reduce falls by 17% and higher doses of cholecalciferol (800–2000 IU/daily) reduce hip fracture risk by 30%. Daily, weekly or 4 monthly regimens appear effective, but annual high dose administration should be avoided. A vitamin D level of >60 nmol/L is required for falls and fracture prevention with the benefit of additional calcium supplementation uncertain.

**Notes**

- Strongly recommended based on high quality evidence (NHMRC level A), relevant to most older adults, easily implementable
- Strongly recommended based on high quality evidence (NHMRC level A), relevant to subpopulations of older adults, implementation dependent on service availability
- Recommended based on good evidence (NHMRC level B), relevant to subpopulations of older adults, implementation requires application of practice points
- Good practice point = Recommendation based on expert opinion with limited evidence, relevant to sub-population, complex to implement
requiring anti-osteoporosis treatment should have supplemental vitamin D and calcium when dietary intake is inadequate.28

**Reduced benzodiazepine use**

Psychoactive medications are taken by 22% of community dwelling older people and there is strong evidence they increase the risk of falls.36,37 There is no evidence that shorter acting benzodiazepines, selective serotonin reuptake inhibitors (SSRI) antidepressants and atypical antipsychotics are safer in terms of fall risk than earlier generation drugs.38 Psychoactive drug withdrawal can reduce falls by 66%.8 Almost 1 in 5 older adults take benzodiazepines long term (>4.5 years) despite a lack of evidence supporting efficacy beyond the short term.40 A meta-analysis which included the newer Z compounds (eg. zolpidem, zopiclone) demonstrated that the small sleep benefits were outweighed by adverse effects including fractures and motor vehicle accidents.41 Recent data associates the use of such sedatives with higher rates of falls, fractures, death and cancer.42,43 In contrast, cognitive behavioural therapy and sleep restriction are effective strategies for treating long term insomnia in older people.44 Prolonged release melatonin has been approved for adults >55 years of age with primary insomnia and poor quality sleep and does not result in next day impairment or rebound insomnia.45 Although benzodiazepine withdrawal is challenging, 18% of older adults quit by themselves after receiving written advice from their GP, and 62% of patients for whom this is insufficient but enrol in a stepped withdrawal program achieve cessation.46 The approach begins with transfer to equivalent diazepam dose, followed by a dose reduction of 25% per week with five consultations. Meta-analysis supports this stepped withdrawal method.47 In recent years, melatonin has been used by clinicians to support sedative withdrawal, which also appears effective.48

**Optimised vision**

Visual impairment is an independent risk factor for falls and fractures. Multifocal spectacles increase falls risk by distorting the lower visual field (Figure 1).49 Adults who undertake regular outdoor activity can reduce their falls risk by using single lens distance glasses instead of multifocals when going outside or to an unfamiliar environment.50 This advice however, increases falls risk in less active adults. Improving spectacle prescription alone has not resulted in falls prevention. Short waiting time for first eye cataract surgery is an effective falls and fracture prevention strategy.8

---

**Home modification**

Home safety modifications in association with transfer training and education are effective in high-risk populations8 such as patients with poor vision or those recently hospitalised.51 The benefits are greater when delivered as part of a multifactorial strategy.14

**Falls prevention strategies in residential aged care settings**

Falls rates are high in residential aged care facilities (RACFs), with 1 in 2 residents falling within a 6 month period.52 Residents have increased rates of cognitive impairment, continence problems, comorbidities and polypharmacy, which contribute to the increased falls risk. The evidence for falls prevention is outlined in Table 3.

Vitamin D deficiency is very high in Australian RACF residents, with 89% having a vitamin D level <60 nmol/l.53 Falls and fractures can be prevented with cholecalciferol supplementation (800–2000 Iu/day) given to all residents, with the requirement for calcium supplementation uncertain.34,53 In Australia, there is no uniform approach to implementation of this evidence: other countries have addressed this using routine administration of oral cholecalciferol 50 000 Iu monthly (not routinely available in Australia).54 The expert panel recommended that vitamin D level should not be tested or monitored and the only contraindication was known hypercalcaemia.

---

**Table 4. Characteristics of effective exercise programs**13

- Moderate or high challenge to balance (eg. tai chi, Otago Exercise Programme)
- 2 hours/week on an ongoing basis
- Home or group setting
- Optional strength training: cognitive and functional benefits
- Brisk walking is not recommended for high risk individuals

---

**Figure 1. Distortion of lower vision field in a patient wearing multifocal spectacles**
Changing medication prescription may reduce falls in RACFs. One randomised controlled trial using pharmacist review followed by written recommendations to the GP resulted in drug changes and decreased falls, with 75% of the recommendations accepted by the GP. Although regular pharmacist reviews occur in Australia, studies suggest 43% of RACF residents are prescribed at least one inappropriate medication.

The evidence for exercise programs preventing falls for RACF residents is inconclusive. As some studies show an increase in falls rate, individuals capable of participation in exercises should be monitored if these are adopted. Multifactorial assessment and intervention can be effective when delivered by a multidisciplinary team. Hip protectors reduce hip fractures when worn, however, their effectiveness as an injury prevention strategy is not established, as programs are hampered by poor acceptance and adherence.

**Key points**

- Challenging balance exercise for 2 or more hours per week on an ongoing basis reduces falls risk in older adults living in the community.
- Daily 800–2000 IU vitamin D supplementation prevents falls and fractures in those with vitamin D levels <60 nmol/L, regardless of living location.
- Benzodiazepine withdrawal, occupational therapy home modifications, expedited cataract procedure and restricted multifocal spectacle use outdoors for active older adults are effective single interventions to reduce falls risk.
- High risk patients with recurrent, unexplained or injurious falls should be considered for specialist referral and multidisciplinary intervention.
