Early response to psychological trauma
What GPs can do

Background
There is a high prevalence of psychological trauma exposure among primary care patients. General practitioners are well placed to provide appropriate support for patients coping with trauma.

Objective
This article outlines an evidence-based early response to psychological trauma.

Discussion
Psychological first aid is the preferred approach in providing early assistance to patients who have experienced a traumatic event. General practitioners can be guided by five empirically derived principles in their early response: promoting a sense of safety, calming, self efficacy, connectedness and hope. Structured psychological interventions, including psychological debriefing, are not routinely recommended in the first few weeks following trauma exposure. General practitioner self care is an important aspect of providing post-trauma patient care.

Keywords
mental health; stress, psychological; psychiatry; mind-body and relaxation techniques

A traumatic event is defined as one in which an individual experiences, witnesses, or is confronted with actual or threatened death or serious injury, such as a car or other serious accident, physical or sexual assault, war or torture, or natural disaster. These events are quite common; approximately three-quarters of Australians experience a traumatic event at some point in their lives, and the majority experience more than one.1

Although post-traumatic stress disorder is often thought of as the signature disorder in the aftermath of a traumatic event, in fact, a range of mental health disorders can develop, including depression, generalised anxiety, panic, agoraphobia and substance use disorders.2 Initial acute distress is to be expected and, in the early days and weeks, many people will experience difficulties with sleep or concentration, feel anxious, jumpy or irritable, or get very upset when they think about the event. However, a ‘resilient’ trajectory with only transient distress and minimal impact on functioning is the most common outcome.3

Among people with persistent symptoms and impaired functioning, a significant proportion will display a ‘recovery’ trajectory and return to their usual level of functioning in the ensuing months without the need for formal mental health interventions.4 Only relatively few people go on to develop chronic mental health problems following exposure to a traumatic event.2 Risk factors for development of more chronic mental health disorders include pre-existing mental health problems, severity of trauma exposure, lack of social support and life stressors.5,6

Given the high prevalence of trauma exposure among primary care patients,7,8 general practitioners (GPs) are well placed to support and monitor the wellbeing of these individuals, and to deliver simple interventions to those experiencing acute distress. In doing so, GPs can help patients to better cope and return to healthy functioning, and may prevent the development of more persistent mental health problems.

Stepped-care approach
A stepped-care approach is recommended for GPs and other practitioners when providing assistance following trauma. This facilitates the provision of an appropriate level of support to
What is reasonably clear from the research evidence is that structured psychological interventions, such as psychological debriefing (which encourages individuals to recount the traumatic event and their responses in some detail), should not be offered on a routine basis in the first few weeks following trauma. Psychological debriefing as an early intervention after trauma is not effective in preventing post-traumatic mental health problems, and may be counterproductive for some people.

What should GPs do immediately following a traumatic event?

There is no standard formula for assisting people to better cope with trauma. They should be supported in using strategies and resources that suit them and that are readily available. Consistent with the approach of PFA, GPs can be guided by and promote five empirically derived principles: a sense of safety, calming, self-efficacy, connectedness and hope. Examples of advice or reassurance GPs can provide in relation to each of these principles can be found in Table 1.

3. Formal mental health interventions – suitable for patients in the weeks and months following trauma with persistent and more severe distress. A small but significant number of patients will require this level of intervention.

2. Simple psychological strategies – suitable for patients in the weeks and months following trauma with persistent mild to moderate severity distress. This level focuses on promoting recovery, secondary prevention, and early identification of mental health problems.

1. Early response: Advice and support – suitable for patients who display acute distress in the days and weeks following trauma. Most people exposed to trauma will only require this level of intervention.

Evidence-informed early response to trauma

International clinical practice guidelines for the management of psychological trauma recommend psychological first aid (PFA) as the preferred approach to providing early assistance to people who have experienced a traumatic event. PFA seeks to:

- reduce initial distress
- address basic needs (e.g., comfort, information, practical and emotional support)
- promote adaptive coping (e.g., problem solving)
- encourage engagement with existing social supports.

While this approach has been endorsed by many experts in post-traumatic mental health, it should be noted that the effectiveness of PFA to promote recovery and prevent the development of more serious mental health problems has not been tested empirically. However, the approach can be broken down into a number of separate components, many of which are supported by research.
FOCUS Early response to psychological trauma – what GPs can do

Heightened arousal, anxiety or other emotions that can undermine confidence and active coping. There are a number of helpful calming strategies that GPs can provide, such as:

- teaching patients to use controlled breathing when anxious (Table 2)
- ‘normalising’ psychological reactions to such events
- encouraging sufficient rest, exercise and a healthy diet
- assisting patients to schedule enjoyable and relaxing activities.

It is also important to encourage the patient to avoid unhelpful coping strategies such as substance use and social withdrawal.

Cautious and time-limited use of prescribed medications (eg, benzodiazepines) may be required to reduce severe arousal, insomnia and distress. However, if benzodiazepines are prescribed, the course of treatment should be kept as brief as possible due to the risk of tolerance and dependency. There is no evidence to support the practice of routinely offering medication to prevent post-traumatic mental health problems. 12

**Self efficacy**

After experiencing a traumatic event, patients may present to their GP feeling overwhelmed and unable to prioritise or cope with a range of practical and emotional concerns. For example, following a natural disaster, patients are frequently concerned about lost possessions, organising childcare and schooling, completing insurance forms and lack of employment. When promoting a sense of self efficacy with a patient, GPs can:

- highlight those aspects of the situation that the person has some control over

**Table 1. Examples of helpful things for GPs to say to patients when providing early response following trauma**

<table>
<thead>
<tr>
<th>Sense of safety</th>
<th>That was then, you’re safe now. I’ve been informed by the authorities that the threat of danger has passed. I don’t know the whereabouts of your parents, but let’s see if we can find out some more information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calming</td>
<td>Those distressing reactions you describe are quite common; most people will have similar reactions for days if not weeks after a very stressful event. It’s very upsetting at times for you, but that doesn’t mean that you’re weak or going crazy; it’s a normal stress response to a very scary experience. What helps you to feel calm and take your mind off things? Looking after yourself, and spending some relaxing time with the family, can really be very helpful during this tough time</td>
</tr>
<tr>
<td>Self efficacy</td>
<td>I understand that you feel overwhelmed. Let’s see if we can come up with at least three things that you do have some control over at the moment. What has helped in the past when you’ve had to deal with a lot of stress? What hasn’t been so helpful? You’ve obviously got a lot on your plate at the moment. What’s the priority problem that you think you could tackle first? I can see that you’re wanting everything to return to normal as soon as possible. But you may want to pace yourself for a period so that you don’t put yourself under any additional stress</td>
</tr>
<tr>
<td>Connectedness</td>
<td>We know that having people that we can rely on and enjoy spending time with is a very helpful for recovery. Is there some time over the next week when you could catch up with your friend? It’s up to you of course, but if you’d like to talk about what happened then I’m a good listener. I understand that you don’t feel comfortable receiving government assistance just now. But it’s there if you change your mind</td>
</tr>
<tr>
<td>Promoting hope</td>
<td>I’m confident that you’ll get through this. Let’s monitor how you’re going but I would expect that within a week we’ll see things start to settle down. Well done. I think you’re doing a great job of staying positive</td>
</tr>
</tbody>
</table>

---

**Table 2. Instructions for controlled breathing to promote calming**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>At the first sign of anxiety, inhale and hold your breath for 4 seconds (don’t take a deep breath)</td>
</tr>
<tr>
<td>2</td>
<td>Breathe out and say the word ‘relax’ to yourself in a calm, soothing manner</td>
</tr>
<tr>
<td>3</td>
<td>Breathe in and out slowly, using a 6-second cycle of breath, ie. breathe in for 3 seconds and out for 3 seconds</td>
</tr>
<tr>
<td>4</td>
<td>Say the word ‘relax’ to yourself every time you breathe out</td>
</tr>
<tr>
<td>5</td>
<td>At the end of each minute, hold your breath again for 10 seconds and then continue breathing in the 6-second cycle</td>
</tr>
<tr>
<td>6</td>
<td>Continue breathing in this way until all the symptoms of anxiety have gone. If you commence controlled breathing as soon as you notice the first sign of anxiety, the symptoms should subside within a few minutes. The more you practise this controlled breathing, the better you will become at using it. Sometimes, you will notice that symptoms of anxiety return after a short while. That’s okay; just do your controlled breathing again for as long as it takes to settle</td>
</tr>
</tbody>
</table>

---
• remind the person about past experiences of successfully coping with stressful situations
• encourage the person to actively address problems and solve one problem at a time
• assist the person to ‘recalibrate’ their expectations of themselves.

**Connectedness**

Support from family, friends and community services is a strong protective factor and enhances recovery following trauma.5,6 There are many different forms of social support (eg. emotional support, material and physical assistance, a sense of belonging), and people can derive benefit from receiving support and from helping and connecting with others. GPs can help to promote a patient’s connectedness by:
• explaining the known benefits of social support
• encouraging the person to identify opportunities to spend time with family and friends
• telling the person that they may find talking to others helpful, but should do so when they feel ready
• directing and referring the person to appropriate community support services
• anticipating that some people will not feel deserving of assistance.

**Promoting hope**

Many patients seen by their GP in the days and weeks following disaster or trauma will feel pessimistic and defeated by their recent experiences, and may have difficulties envisaging a future for themselves or their family. A GP has an early opportunity to promote hope about the patient making a successful recovery, by conveying that:
• most people recover with time by using helpful coping strategies and with the support of family and others
• for many people, distressing psychological reactions are transient
• the patient has strengths, such as their ability to cope under stress or their available social supports.

**Ongoing monitoring and GP self care**

Given the variability in mental health trajectories following trauma, active and ongoing monitoring of patients by GPs is often needed for early detection of stalled recovery and/or persistent mental health difficulties that require more intensive treatment. It is important to be aware that patients experiencing persistent difficulties in recovery may often present to GPs with non-specific physical health complaints.

Providing care in the aftermath of a traumatic event can place significant demands on GPs. For example, GPs may face repeated exposure to traumatic and distressing experiences of others, and in some large scale events, may themselves be members of the affected community. It is therefore important that GPs look after their own mental health, by employing the self-management strategies that they encourage their patients to use.

**Key points**

• Only a minority of people develop chronic mental health problems following exposure to a traumatic event.
• GPs are well placed to support and monitor primary care patients following trauma exposure.
• Psychological first aid is the preferred approach to providing early assistance to people who have experienced a traumatic event.
• Early advice and support provided by GPs can be guided by the following principles: a sense of safety, calming, self efficacy, connectedness and hope.
• GP self care is an important aspect of providing post-trauma patient care.
